

# Information Management Systems (ECSE211L)

(Introduction to DBMS –Part 2)

# Data Abstraction

- Data Abstraction refers to the process of **hiding irrelevant details** from the user.
- Database systems are made-up of **complex data structures**. To ease the user interaction with database, the developers hide internal irrelevant details from users. This process of hiding irrelevant details from user is called data abstraction.
- Hiding certain details of how the data are stored.
- There are mainly **three levels of data abstraction** and we divide it into three levels in order **to achieve Data Independence**.

# Level of Abstraction

Levels of Data Abstraction

# Data Levels and their Roles (Data Abstraction)

- 1. Physical level**— This is the lowest level of data abstraction. It describes **how data is actually stored in database**. You can get the complex data structure details at this level. Implementation details such as indexing methods like B+ trees or hashing and access methods such as sequential or random access used are described in this level.
- 2. Conceptual/logical level** At this level, we can see **what data is stored** in the database without knowing the implementation details such as the data structures and tree implementations. This level also tells us about the relations between the different fields and database tables.
- 3. View level** — This is the highest level from the three levels of data abstraction. In this, only the part of the data which are relevant to the users is accessible. **What part of the data is seen** by a specific application. This level tells the application about how the data should be shown to the user.

# Three Level Of Abstraction

# Example of Data abstraction

Type of Schema	Implementation
External Schema	View 1: Course info(cid:int,cname:string) View 2: studeninfo(id:int. name:string)
Conceptual Shema	Students(id: int, name: string, login: string, age: integer) Courses(id: int, cname.string, credits:integer) Enrolled(id: int, grade:string)
Physical Schema	<ul style="list-style-type: none"><li>• Relations stored as unordered files.</li><li>• Index on the first column of Students.</li></ul>

# Schema and Instance

- The data which is stored in the database at a particular moment of time is called an instance of the database.
- The overall design of a database is called schema. A schema contains schema objects like table, views, stored procedure, etc.
- Similar to types and variables in programming languages

- Schema

- **Logical Schema**-the overall logical structure of the database
- Analogous to type information of a variable in a program
- Example: The database consists of information about a set of customers and accounts in a bank and the relationship between them

- **Customer Schema**

Name	Customer ID	Account #	Aadhar ID	Mobile #
------	-------------	-----------	-----------	----------

- **Account Schema**

Account #	Account type	Interest rate	Min Bal.	Balance
-----------	--------------	---------------	----------	---------

- **Physical Schema:** the overall physical structure of database.

# Schema and Instance

- Instance
  - The actual content of the database at a particular point in time
  - Analogous to values of a variable

- **Customer Schema**

Name	Customer ID	Account #	Aadhar ID	Mobile #
Pawan	1234	943234	223454321654	9934567378
Rahul	4321	343242	342323542342	9823234522

- **Account Schema**

Account #	Account type	Interest rate	Min Bal.	Balance
943234	Savings	4%	5000	6543
343242	Current	0.0%	0	234455

# Data Independence

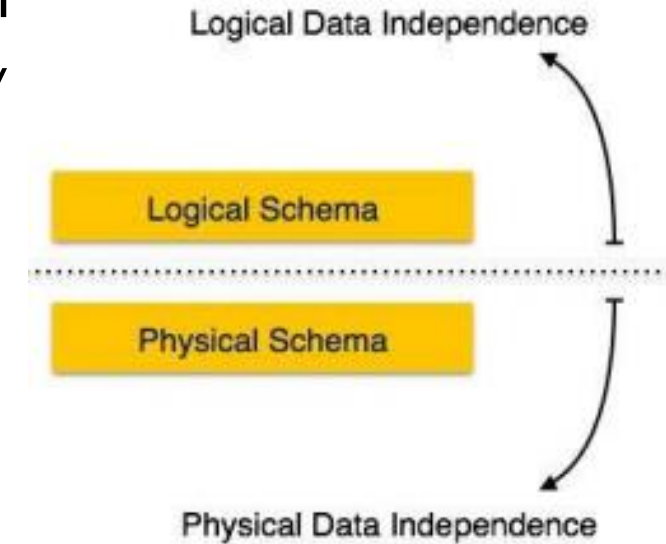

- Data Independence is defined as a property of DBMS that helps you to change the Database schema at one level of a database system without requiring to change the schema at the next higher level. Data independence helps you to keep data separated from all programs that make use of it.
- A database system normally contains a lot of data in addition to users' data. For example, it stores data about data, known as metadata, to locate and retrieve data easily . It is rather difficult to modify or update a set of metadata once it is stored in the database. But as a DBMS expands, it needs to change over time to satisfy the requirements of the users. If the entire data is dependent, it would become a tedious and highly complex job.

# Physical and Logical Data Independence

**Physical data independence** It is defined as the ability to make changes in the structure of the lowest level of the Database Management System (DBMS) without affecting the higher-level schemas. Hence, modification in the Physical level should not result in any changes in the Logical or View levels.

## Examples of changes under Physical Data Independence

- Using a new storage device like Hard Drive or Magnetic Tapes
- Modifying the file organization technique in the Database
- Switching to different data structures.
- Changing the access method.
- Modifying indexes.
- Changes to compression techniques or hashing algorithms.
- Change of Location of Database from say C drive to D Drive

# Physical and Logical Data Independence

- **Logical Data Independence** is the ability to change the conceptual schema without changing
  - External views
  - External API or programs
- Any change made will be absorbed by the mapping between external and conceptual levels.
- **Examples of changes under Logical Data Independence**

Due to Logical independence, any of the below change will not affect the external layer.

- Add/Modify/Delete a new attribute, entity or relationship is possible without a rewrite of existing application programs
- Merging two records into one
- Breaking an existing record into two or more records

- A main purpose of DBMS is to provide \_\_\_\_\_ view of data to user.
  - Abstract
  - Partial
  - Complete
  - None of these

- A main purpose of DBMS is to provide \_\_\_\_\_ view of data to user.
  - **Abstract**
  - Partial
  - Complete
  - None of these

- \_\_\_\_\_ means to hide certain details of how data is stored and maintain.
  - Data Isolation
  - Data Integrity
  - Data Abstraction
  - None of these

- \_\_\_\_\_ means to hide certain details of how data is stored and maintain.
  - Data Isolation
  - Data Integrity
  - **Data Abstraction**
  - None of these

- \_\_\_\_\_ of abstraction explains how data is actually stored and describes the Data Structure and Access methods used by database.
  - View Level
  - Physical Level
  - Conceptual Level

- Map of concepts and their relationships is represented by \_\_\_\_\_ Schema.
  - Physical Schema
  - None of these
  - Conceptual Schema

- Map of concepts and their relationships is represented by \_\_\_\_\_ Schema.
  - Logical Schema
  - Physical Schema
  - None of these
  - **Conceptual Schema**

- Collection of information stored in database at particular instance of time is called as \_\_\_\_\_.
- Instance of Database
- Database Schema
- Data Structure
- Objects in Database

- Collection of information stored in database at particular instance of time is called as \_\_\_\_\_.

- **Instance of Database**
- Database Schema
- Data Structure
- Objects in Database

# Data Models

- A collection of tools for describing the structure of data base,
  - Data
  - Data relationship
  - Data constraints
- Relational model (**we focus in this course**)
- Entity relationship data model(mainly for database design)
- Object based data model (object oriented and object relational)
- Semi- structure data model (XML)
- Other older models
  - Network model
  - Hierarchical model

# Relational model

**Table** also called **Relation**

The diagram shows a table with three columns: CustomerID, CustomerName, and Status. The first row is highlighted in yellow. Annotations include: 'Primary Key' pointing to CustomerID, 'Domain' with 'Ex: NOT NULL' pointing to CustomerName, 'Column OR Attributes' pointing to the column headers, 'Tuple OR Row' pointing to the first data row, and 'Total # of rows is Cardinality' pointing to the first three rows. Below the table, 'Column OR Attributes' is repeated with 'Total # of column is Degree' below it.

CustomerID	CustomerName	Status
1	Google	Active
2	Amazon	Active
3	Apple	Inactive

**Primary Key**

**Domain**  
Ex: NOT NULL

**Column OR Attributes**

**Tuple OR Row**

Total # of rows is **Cardinality**

**Column OR Attributes**

Total # of column is **Degree**

# DBMS Languages

- DBMS system provides a Data Definition Language to specify the database schema and a data-manipulation language to express database queries and updates.
- In Practice, the DDL and DML are not to separate languages; instead they simply form parts of a single database language, such as the widely used SQL language.

# Data Definition Language

Specification notation for defining the database schema

- E.g.

```
create table account (  
                account-number char(10),balance integer)
```

- DDL compiler generates a set of tables stored in a data dictionary
- Data dictionary contains metadata (i.e., data about data)
  - database schema
  - Data storage and definition language
    - language in which the storage structure and access methods used by the database system are specified
    - Usually an extension of the data definition language

# Data Manipulation Language:

- Language for accessing and manipulating the data organized by the appropriate data model
- Two classes of languages
  - Procedural – user specifies what data is required and how to get those data
  - Nonprocedural – user specifies what data is required without specifying how to get those data
- SQL is the most widely used query language

# Database Languages

```
SELECT Chair
FROM Faculty, Department
WHERE Faculty.name = "Ken Noname"
      AND Faculty.Dept = Department.Dept
```

Data definition language (DDL) ~ like type definitions in C or C++

Data Manipulation Language (DML)

Query (SELECT)

UPDATE <relation name>

SET <attribute> = <new-value>

WHERE <condition>

Faculty	
Name	Dept

Department	
Dept	Chair

SQL

**Thank you**
